Description: .050" [1.27mm] SEARAY™ High-Speed High-Density Array Cable Assembly, 36 AWG 50ohm Coax Cable

Cable Assembly Overview

The SEAC Cable Assembly is constructed using 36 AWG 50-ohm coax cable and is designed for high speed, micro pitch application. The SEAC series cable assemblies are available in 4, 6, 8, and 10 row option; with a maximum of 240 pins, 50% of which are tied to ground return. The minimum cable length is 152.4 mm (6.0"). The data in this report is only applicable to 250 mm and 1000 mm cable lengths.

The 180 pin (6x30) test sample consists of nine micro ribbon coax cables separated into three groups of three ribbons each; resulting in a total of ninety signal lines. At each end of the cable there is an open pin field array that mates with Edge Rate™ contacts. Each open pin field array has three small transition PCBs that provide for termination of the ribbon cables as well as pads that are compatible with Edge Rate™ contacts. The pads are on a 1.27 mm pitch, and half the pads are dedicated to ground. The transition boards use green PCBs at End 1 and red PCBs at END 2.

The SEAC cable assemblies were tested by mating it to a SEAF-30-05.0-S-06-2-N-K-TR socket at each end. One sample of each length assembly was tested. The actual part numbers that were tested are shown in Table 1, which also identifies End 1 and End 2 of each assembly. A relative sample picture is shown in Figure1. Two lines, an Inner Path and an Outer Path of the sample were tested. End 1 is at the left with the assembly stretch out and viewed so that the cable label containing the assembly part number can be read in normal fashion from left to right.

Length	Part Number	End 1	End 2

Characterization Details

This report presents data that characterizes the signal integrity response of a cable assembly in a controlled printed circuit board (PCB) environment. All efforts are made to reveal typical best-case responses inherent to the system under test (SUT).

In this report, the SUT includes the mating connectors, cable assembly, and footprint effects on a typical multi-layer PCB. PCB effects (trace loss) are de-embedded from test data. Board related effects, such as pad-to-ground capacitance, are included in the data presented in this report.

Additionally, intermediate test signal connections can mask the cable assembly's true performance. Such connection effects are minimized by using high performance test cables and adapters. Where appropriate, calibration and de-embedding routines are also used to reduce residual effects.

Differential and Single-Ended Data

Most Samtec cable assemblies can be used successfully in both differential and single-ended applications. However, electrical performance will differ depending on the signal drive type. In this report, data is presented for "GSG" Single-Ended drive configuration only.

Cable assembly Signal to Ground Ratio

Samtec cable assemblies are most often designed for generic applications and can be implemented using various signal and ground pin assignments. In high speed systems, provisions must be made in the interconnect for signal return currents. Such paths are often referred to as "ground". In some cable assemblies, a ground plane or blade, or an outer shield, is used as the signal return, while in others, cable assembly pins are used as signal returns. Various combinations of signal pins, ground blades, and shields can also be utilized. Electrical performance can vary significantly depending upon the number and location of ground pins.

In general, the more pins dedicated to ground, the better electrical performance will be. But dedicating pins to ground reduces signal density of a cable assembly. Therefore, care must be taken when choosing signal/ground ratios in cost or density-sensitive applications.

Series: SEAC

Description: .050" [1.27mm] SEARAY™ High-Speed High-Density Array Cable Assembly,
36 AWG 50ohm Coax Cable

For this cable assembly, the following array configurations are evaluated:

Single-Ended Impedance:

- Long Path (furthest from test fixture)
- Short Path (closest to test fixture)

Single-Ended Crosstalk:

- Across Row: "Xrow": (from one row of terminals to the other row)

See [Appendix C](#) – Product and Test System Descriptions for details

Other configurations can be evaluated upon request. Please contact sig@samtec.com for more information.

In a real system environment, active signals might be located at the outer edges of the signal contacts of concern, as opposed to the ground signals utilized in laboratory testing. For example, in a single-ended system, a pin-out of "SSSS", or four adjacent single ended signals might be encountered as opposed to the "GSG" and "GSSG" configurations tested in the laboratory. Electrical characteristics in such applications could vary slightly from laboratory results. But in most applications, performance can safely be considered equivalent.

Signal Edge Speed (Rise Time)

In pulse signaling applications, the perceived performance of the interconnect can vary significantly depending on the edge rate or rise time of the exciting signal. For this report, the fastest rise time used was 30 ps. Generally, this should demonstrate worst-case performance.

In many systems, the signal edge rate will be significantly slower at the cable assembly than at the driver launch point. To estimate interconnect performance at other edge rates, data is provided for several rise times between 30 ps and 100 ps.

Unless otherwise stated, measured rise times were at 20%-80% signal levels.

36 AWG 50ohm Coax Cable

Frequency Domain Data

Frequency Domain parameters are helpful in evaluating the cable assembly system's signal loss and crosstalk characteristics across a range of sinusoidal frequencies. In this report, parameters presented in the Frequency Domain are Insertion Loss, Return Loss, Near-End and Far-End Crosstalk, and Mode Conversion. Other parameters or formats, such as VSWR or S-Parameters, may be available upon request. Please contact our Signal Integrity Group at sig@samtec.com for more information.

Frequency performance characteristics for the SUT are generated directly from network analyzer measurements.

Time Domain Data

Time Domain parameters indicate Impedance mismatch versus length and signal propagation time in a pulsed signal environment.

Impedance mismatch versus length is measured by DSA8200 Digital Serial Analyzer. Board related effects, such as pad-to-ground capacitance and trace loss, are included in the data presented in this report. The impedance data is provided in [Appendix B](#) of this report.

The measured S-Parameters from the network analyzer are post-processed using Keysight ADS to obtain the time domain response for signal propagation time. The Time Domain procedure is provided in [Appendix D](#) of this report. Parameters or formats not included in this report may be available upon request. Please contact our Signal Integrity Group at sig@samtec.com for more information.

In this report, propagation delay is defined as the signal propagation time through the cable assembly, mating connectors, and connector footprint. It also includes 10 mils of PCB trace on each connector side. Delay is measured at 100 picoseconds signal rise-time. Delay is calculated as the difference in time measured between the 50% amplitude levels of the input and output pulses.

Data for other configurations may be available. Please contact our Signal Integrity Group at sig@samtec.com for further information.

Additional information concerning test conditions and procedures is located in the appendices of this report. Further information may be obtained by contacting our Signal Integrity Group at sig@samtec.com.

Product Description

Product test samples are 1.27 mm SEARAY™ High-Speed High-Density Array Cable Assemblies. The part numbers are SEAC-030-06-10.0-TU-TU and SEAC-030-06-39.4-TU-TU. They mate with SEAF-XX-05.0-X-XX-X-N-K-TR. A photo of the mated test article mounted to SI test boards is shown below. The cable assembly terminations had a particular signal line configuration. The respective END 1 signal line numbers that were made available as test ports and that were used during the testing are shown in Table 3 below. All adjacent lines are terminated where applicable.

Test System Description

The test fixtures are composed of four-layer FR-4 material with 50Ω signal trace and pad configurations designed for the electrical characterization of Samtec high speed cable assembly products. A PCB mount SMA connector is used to interface the VNA test cables to the test fixtures. Optimization of the SMA launch was performed using full wave simulation tools to minimize reflections. Two test fixtures are specific to SEAC series cable assemblies and identified by part numbers PCB-106736-SIG-01A and 01B. The Auto Fixture Removal (AFR) calibration structures designed specifically for the SEAC series are located on PCB-106736-SIG-01A test board. Displayed on the following pages is the information for the SEAC and AFR calibration structure and directives for the mating SEAC fixtures.

Appendix D – Test and Measurement Setup

For frequency domain measurements, the test instrument is the Agilent N5230C PNA-L network analyzer. Frequency domain data and graphs are extracted from the instrument by AFR application. Post-processed time domain data and graphs are generated using convolution algorithms within Agilent ADS. The network analyzer is configured as follows:

Start Frequency – 10 MHz
Stop Frequency – 20 GHz

Number of points -2000
IFBW – 1 KHz

With these settings, the measurement time is approximately 20 seconds.

Appendix E - Frequency and Time Domain Measurements

Frequency (S-Parameter) Domain Procedures

The quality of any data taken with a network analyzer is directly related to the quality of the calibration standards and the use of proper test procedures. For this reason, extreme care is taken in the design of the calibration standards, the SI test boards, and the selection of the PCB vendor.

The measurement process begins with a measurement of the AFR calibration standards. A coaxial SOLT calibration is performed using an N4433A E-CAL module. This measurement is required in order to obtain precise values of the line standard offset delay and frequency bandwidths. Measurements of the 2x through line standard can be used to determine the maximum frequency for which the calibration standards are valid. For the SEAC test boards, this is greater than 20 GHz.

The figure below shows how the 2X THRU reference traces is utilized to compensate for the losses due to the coaxial test cables and the test fixture during testing. The calibration board is characterized to obtain parameters required to define the 2X THRU.

Series: SEAC

36 AWG 50ohm Coax Cable

Time Domain Procedures

Mathematically, Frequency Domain data can be transformed to obtain a Time Domain response. Perfect transformation requires Frequency Domain data from DC to infinity Hz. Fortunately, a very accurate Time Domain response can be obtained with bandwidth-limited data, such as measured with modern network analyzer.

The Time Domain responses were generated using Agilent ADS 2016 update 1. This tool has a transient convolution simulator, which can generate a Time Domain response directly from measured S-Parameters. An example of a similar methodology is provided in the Samtec Technical Note on domain transformation.

http://www.samtec.com/Documents/WebFiles/Technical_Library/Reference/Articles/tech-note_using-PLTS-for-time-domain-data_web.pdf

Propagation Delay (TDT)

The Propagation Delay is a measure of the Time Domain delay through the cable assembly and footprint. A step pulse is applied to the touchstone model of the cable assembly and the transmitted voltage is monitored. The same pulse is also applied to a reference channel with zero loss, and the Time Domain pulses are plotted on the same graph. The difference in time, measured at the 50% point of the step voltage is the propagation delay.

Impedance (TDR)

Measurements involving digital pulses are performed using either Time Domain Reflectometer (TDR) or Time Domain Transmission (TDT) methods. The TDR method is used for the impedance measurements in this report.

The signal line(s) of the SUT's is energized with a TDR pulse and the far-end of the energized signal line is terminated in the test systems characteristic impedance (e.g.; 50Ω or 100Ω terminations). By terminating the adjacent signal lines in the test systems characteristic impedance, the effects on the resultant impedance shape of the waveform is limited. The "best case" signal mapping was tested and is presented in this report.
